1. Introduction

What Is MiniGUI

MiniGUI (http://www.minigui.com), developed by FMSoft, is a lightweight graphics user interface (GUI) support system for embedded systems and smart IoT devices. Since the first release under the GPL license at the beginning of 1999, MiniGUI has been widely used in handheld terminals (mobile phones and PDAs), set top boxes, industry control systems, industry instruments, portable media players, digital photo frames, information terminals, and so on.

At the same time, MiniGUI has become a cross-operating-system GUI system; it can run on Linux/uClinux, eCos, VxWorks, pSOS, ThreadX, Nucleus, OSE, and even uC/OS-II, also on the Win32 platform; the hardware platforms which have been tested include Intel x86 32/64-bit, ARM 32/64-bit (e.g., ARMv7 and ARM Cortex-A7), MIPS, PowerPC, and M68k (DragonBall/ColdFire). MiniGUI V2.0.x provides the full multi-process support for high-end embedded devices based on embedded Linux, which brings MiniGUI into the high-end embedded market. MiniGUI V3.0 introduces many important enhancements, such as BIDI text display support, transparent control, independent scroll control, Unicode pre-rendered font (UPF), bitmap font, and new components including mGUtils, mGPLus, mGEff, and mGNCS. MiniGUI V3.2.x provides support for 64-bit architectures.

MiniGUI is “a cross-operating-system graphics user interface support system for embedded systems and smart IoT devices”, and “an embedded graphics middleware”. So far, MiniGUI has been authorized by the most famous telecommunication equipment supplier in China, the biggest TV set manufacturer in China, the main 3G/4G baseband chip, and many SoC vendors in the world. MiniGUI has been widely adopted and applied by the leading manufacturers in the following fields: consumer smart device, industry instrument, medical equipment, and the military industry. At the same time, MiniGUI has been recognized by global embedded devices developers, and is sold overseas including USA, EU, Japan, South Korea, Chinese Taiwan, India, and Malaysia. MiniGUI has become the industrial de-facto standard in the field of embedded graphics middleware. It is worth mentioning that about 60 percent of TD-SCDMA mobile phones used MiniGUI as their embedded graphical platform to support 3G application such as browser and videophone in the year 2010. Among these models of TD-SCDMA mobile phones include T68 of Hisense and U85 of ZTE, and so on.

FMSof not only releases MiniGUI under GPL\(^1\), but also releases development tools and other key software products for developers of MiniGUI. This document is organized to introduce features and application areas of MiniGUI in detail.

Goals of MiniGUI

We design MiniGUI mainly for embedded systems and smart IoT devices, which usually have small display screens with or without touch panels.

---

\(^1\) The GPL is a widely used free software license, originally written by Richard Stallman for the GNU Project. Please visit http://www.gnu.org in detail.
Generally, the hardware configuration of an embedded system or an IoT device is less lower than a desktop computer. Most of these devices are not shipped with GPUs. On the other hand, with the development of hardware technology, some devices (e.g., smart phones) have shipped with large memories and GPUs, and Linux is the only operating system or kernel for these smart devices.

Therefore, we develop MiniGUI for these goals:

- Keep the configurable and flexible design of MiniGUI, so the developer can not only use MiniGUI for a low-end device, but also for a high-end device which is shipped with a GPU.
- Keep developing miniStudio, the WYSIWYG IDE for MiniGUI, in order to reduce the difficulty and the complexity to develop MiniGUI apps.
- Since MiniGUI 3.2, we will focus on smart devices which run Linux as the operating system.

It is worth noting that, we will try to provide a Python-based runtime framework for smart devices which based on Linux and MiniGUI.

The Origin and Evolution of MiniGUI

Almost twenty years have passed since MiniGUI was launched at the end of 1998. Originally, MiniGUI was designed to provide a simple human-machine interface for a control system, which was based on Linux; no one foresaw that MiniGUI would become a cross-OS embedded GUI system. Fortunately, MiniGUI has been widely used in various projects since launched, and the increasing requirements from practical projects make MiniGUI grow into a cross-OS embedded GUI middleware product gradually.

In December 1998, the initiator of FMSoft, Wei Yongming, began to develop MiniGUI, and applied it in a computerized numerical control (CNC) system.

In March 2000, Lenovo adopted MiniGUI to develop the installer for HappyLinux V1.0 (a Linux distribution). At that time, MiniGUI had been a powerful embedded GUI support system for Linux.

From April 2000 to September 2002, as one of the famous free software, MiniGUI was developed and released under the GPL license.

In September 2002, the core developers of MiniGUI founded Beijing FMSoft Technology Co., Ltd., and started the commercial marketing with the free software.

MiniGUI V1.2.6 and MiniGUI V1.3.0 were released in May 2003 and September 2003 respectively.

In October 2003, MiniGUI was ported to the uClinux and eCos operating systems. Thus, MiniGUI had become a cross-OS embedded GUI system.

In August 2004, HUAWEI (the leading telecommunication equipment provider) used MiniGUI as the platform on set top box (STB), hand-held devices, etc.

In November 2004, FMSoft released MGIS solution for embedded geographic information system (GIS) application.

In January 2005, DaTang Mobile (the designer of TD-SCDMA technical standards) used MiniGUI as MMI solution for TD-SCDMA mobile phone.

In March 2005, the Customized version of MiniGUI (MiniGUI-CMR) and Standard version of MiniGUI (MiniGUI-STD) had been released.
In May 2005, FMSoft and Intel reached an agreement on authorizing to develop its series of new products development and production of "Digital Family".

In July 2005, MiniGUI develop environment based on VxWorks Simulator had been released, which extended the cooperation between FMSoft and WindRiver.

In August 2005, Korea system programmer has become the distributor of FMSoft products officially in Korea, which marked a new stage in the progress for our products towards further internationalization.

In September 2005, FMSoft released the mSpider browser. In September 2005, FMSoft released the eDillo V0.4.0 underlying GNU GPL license.

In January 2006, FMSoft released the component products based on MiniGUI, including \(^{2}\) mGp V1.0, mGi V1.0, and mG3d V1.0.

In February 2006, the embedded browser mSpider V1.6 was released.

In March 2006, FMSoft released MGDesktop V2.5. And Changhong Electric Co., Ltd. used MiniGUI and mSpider to develop DTV and IPTV, which indicated that FMSoft become the leading solution provider on DTV, IPTV, and its related areas.

In May 2006, FMSoft provide the port of MiniGUI for Vxworks.

In June 2006, FMSoft became a strategic partner of AMD; MiniGUI and Fhas were used by AMD as the graphics environment for the referenced design proposal of Argon PMP.

In June 2006, FMSoft integrated MiniGUI with the Real-Time Operating System OSE of Enea. MiniGUI can simplify the design and development of the graphical user interface, which runs on Hand-Held Terminal Device, telecom device, Medical Equipment, STB and Industrial Control system.

In August 2006, FMSoft cooperated with Atmel, which is an international leading semiconductor supplier. MiniGUI was used to develop MMI reference design for a wide range of chips in WiFi field, and it further strengthened FMSoft’s world leading position in WiFi field.

In November 2006, Taiwan Inventec electronic company used MiniGUI to develop the visible IP phone supporting Skype, which promoted FMSoft’s high-end status in digital-medium domain.

In December 2006, in HongKong ITU Telecom World, DaTang Mobile released TD-SCDMA 3G mobile software standard platform Arena, which used MiniGUI and MiniGUI Optional Components as their terminal application develop environment. This symbolized that MiniGUI already became handset de-facto industry standard in TD-SCDMA standard platform.

In December 2006, FMSoft released Embedded Flash Player: mSeal V1.0.

In March 2007, FMSoft released MGDesktop V3.0. In July 2007, FMSoft released the full-featured and high-end embedded browser mDolphin V1.0.

\(^{2}\) It employs another product of FMSoft: Fhas.
In February 2008, FMSoft released MGDesktop V4.0. In June 2008, FMSoft released mDolphin V2.0.

In October 2010, FMSoft released MiniGUI v3.0.12, miniStudio V1.0.8.

In August 2017, FMSoft released the latest source code of MiniGUI V3.0, all MiniGUI components, and mDolphin V3.0 under GPL 2.0/3.0, on GitHub.

In October 2017, FMSoft resumed the development of MiniGUI.

In February 2018, FMSoft released MiniGUI V3.2.0 and miniStudio 1.2.1. MiniGUI 3.2 provides the support for 64-bit platforms.

At present, FMSoft releases MiniGUI V3.0.x and MiniGUI V3.2.x at the same time. Because of change of some APIs, we recommend that for your new projects, please use MiniGUI V3.2.x instead of MiniGUI V3.0.x.

**Typical Application Fields of MiniGUI**

Since the original CNC system to the present popular smart hand-held devices, MiniGUI has been applied in many products. The main application fields of MiniGUI can be divided into the following categories.

**Smart IoT devices**

Figure 1.1 shows a typical smart IoT device, Joopic CamBuddy Plus, based on Linux and MiniGUI. The device is developed by Joobot. Joopic CamBuddy Plus is one of the smartest cloud access device for DSLR (a class of professional digital cameras), and also able to act as a DSLR remote controller. It is shipped with a 4G/LTE module, a high-speed WiFi, a TFT screen, and a touch panel.

2. Features and Advantages of MiniGUI

Technical Features of MiniGUI

MiniGUI is one of the most popular open source GUI systems for embedded systems in the world, providing fully graphics support for embedded Linux system. MiniGUI provides complete multi-process
support for embedded system, and can run under three modes: MiniGUI-processes, MiniGUI-threads and MiniGUI-standalone. The main technical features of MiniGUI are as follow.

**Hardware support**

MiniGUI has been proven to be capable of running smoothly on the embedded systems with such CPUs/SoCs based on x86, ARM, MIPS, PowerPC etc.

- Support for low end video devices such as monochromatic LCD and high end video devices. MiniGUI also provides support for special video devices (such as YUV device) by using graphics engine, which runs under the graphics abstract layer of MiniGUI. No limit for video resolution.
- Support for slave screens. If your system has multiple video devices, you can use one device as the master screen of MiniGUI to create main windows and controls and the other devices as the slave screens. By using GDI APIs of MiniGUI, you can also render text, output graphics to the slave screens.
- Support for all kinds of input devices, including PC keyboard, PC mouse, keypad, touch panel, remote controller, and so on.
- Support for multiple keyboard layouts, including American PC, French, German, Italian, Spanish, and so on.

**Footprint**

- At least 1024KB static memory (FLASH), varies from different configuration options.
- The typical RAM needed by MiniGUI itself are 1024KB. 8MB system RAM is recommended to run a typical embedded application.

**Operating Systems**

- Support for Linux; MiniGUI can run in three runtime modes on Linux: MiniGUI-Processes, MiniGUI-Threads, or MiniGUI-Standalone.
- Support for RTOSes, such as VxWorks, ThreadX, eCos, uC/OS-II, pSOS, ThreadX, Nucleus, OSE; MiniGUI runs in two runtime modes on these RTOSes: MiniGUI-Threads or MiniGUI-Standalone.
- Support for built-in resources. You can compile the resources (bitmaps, icons, and fonts) into the library, so it is unnecessary to read the resources from files. Thus, MiniGUI can be used on some embedded systems without file systems.
- Special support for embedded systems, including the common I/O operations, byte-orders related functions, and so on.

**Windowing sub-system**

- Mature multi-window and messaging mechanism. By using the MiniGUI-Threads mode, it can create the main window in different threads and support for messaging among the threads. By using the MiniGUI-Processes mode, it supports for the multi-process windowing system.
- Support for dialog box and message box.
- Commonly used controls (widgets), including static label, button, single-line and multi-line edit boxes, list box, combo box, menu button, progress bar, property sheet, toolbar, track bar, tree view, list view, month calendar, grid view, animation, icon view, and so on.
- Support for other GUI elements, including menu, acceleration key, caret, timer, etc.

**Graphics sub-system**
✓ Support for enhanced GDI APIs. You can use these APIs to do raster operations, create complex regions, draw or fill ellipses, arcs, and polygons, etc. There are advanced 2D graphics functions available on C99 math library. We can even implement these advanced graphics interfaces on low-end video devices by using “Shadow” engine which runs under the graphics abstraction layer of MiniGUI.

✓ Support for almost all popular image file types including GIF, JPEG, PNG, Win32 BMP, etc. (JPEG and PNG are supported by using libjpeg and libpng respectively).

✓ Support for Windows resource files, for example, Windows bitmap, icon, cursor, etc.

✓ Support for multiple character sets and multiple font types. At present, what are supported include such character sets as ISO8859-1 ~ ISO8859-15, GB2312, BIG5, EUCKR, SHIFT-JIS, UNICODE (UTF-8 and UTF-16 encodings); bitmap fonts such as Qt Pre-rendered fonts, and vector fonts such as TrueType (by using FreeType library).

✓ Input method interface to support special embedded devices. Moreover, input methods for Simplified Chinese are built-in.

Advantages of MiniGUI

Comparing with other embedded graphics systems, MiniGUI has the advantages as follow.

Scalability

The abundant functions and configurability of MiniGUI makes it applicable in low-end products based on the CPU main frequency 30MHz as well as high-end products. The developers can create dashy user interfaces by using the advanced control styles and the skin technology.

The feature of cross-operating-system makes it easy to run MiniGUI on the simplest embedded operating system, such as uC/OS-II, and the modern embedded operating system, such as Linux. Furthermore, MiniGUI provides complete and multi-window system for embedded Linux operating system.

These features make MiniGUI has a strong scalability, which is considered at the begin time of designing MiniGUI, so MiniGUI can not only be applied in simple devices, but also be applied on complicated electronic products.

Light-Weight and Low Resources Consumption

MiniGUI is a light embedded graphical library, and we have considered the hardware situation of embedded devices and the requirement of system resources completely. The size of MiniGUI library can be reduced to about 500 KB or less, and this is very good for the embedded devices.

Besides these, the latest R&D result indicates, MiniGUI is capable of running on a system with 30 MHz CPU and 4MB RAM successfully (on uClinux), which cannot be reached by other embedded graphics systems.

High Performance and High Reliability

The good architecture and optimized graphics interfaces of MiniGUI lead a very fast graphics output. In fact, MiniGUI was designed for real-time systems, taking into consideration the compactness, high performance, and high efficiency from the beginning. MiniGUI has been widely used in many areas, especially in industry production systems. MiniGUI plays an important role in these products or projects.

Since the release of its first version in 1999, MiniGUI has been employed by many products and projects, which, in turn, drive MiniGUI to improve its reliability and robustness constantly.
For the latest successful cases, you could visit the “typical cases” area in the official web site of MiniGUI (http://www.minigui.com).

**Configurability**

GUI systems are expected to be configurable in order to satisfy the different requirements from the embedded systems. Like Linux kernel, MiniGUI have many compilation configuration options, though which we can designate MiniGUI libraries to include and exclude some features. In general, MiniGUI can be customized against the following aspects:

- The target operating system MiniGUI runs on.
- The target hardware platform runs on.
- The runtime mode: MiniGUI-Threads, MiniGUI-Processes, or MiniGUI-Standalone.
- GAL and IAL engines to be used.
- Font types to be supported.
- Charsets to be supported.
- Image file formats to be supported.
- Widgets to be used.
- Window/Widget appearance styles: classic, flat, or fashion style.

These configuration options increase the flexibility of MiniGUI, and you can create the most suitable system based on your requirements.

In summary, MiniGUI is an embedded graphics support system for real time embedded products with high efficiency, reliability, scalability, and configurability. It brings the modern windowing and graphics technologies into the embedded devices. We can summarize the advantages of MiniGUI as follow:

- Support for multiple embedded OSes with great portability.
- Scalable architecture, easy to extend.
- Rich functions, flexible to customize.
- Optimal balance between low footprint and high performance.
- Wide application fields.

**New features of MiniGUI V3.2**

We introduce the following new features in MiniGUI V3.2.

- The support for 64-bit architectures (MiniGUI core and all components).
- mGNCS4Touch, a MiniGUI component which provide some mGNCS-compliant widgets with animations for smart devices with a touch panel.

We modify some APIs in MiniGUI V3.2 in order to support the 64-bit architectures. Therefore, all developers of MiniGUI are recommended strongly to use MiniGUI 3.2.x for new MiniGUI apps.

**New features of MiniGUI V3.0**

MiniGUI V3.0 adds or improves the following features based on former releases:

**Double Buffering Main Window**
When a MiniGUI 3.0 main window has double buffer, you can get the rendering result of the main window in your own buffer. By using double buffer technology, you can use an advance 2D graphics interface or 3D rendering library to get the 3D user experience easily.

**Look and Feel Render (LFRDR)**

MiniGUI V3.0 abandons the old rendering mode which only supports three kinds control style and introduces a new mode of render, namely, Look and Feel Renderer. Renderer defines how to draw the window elements, which is modified based on MiniGUI V2.0. Window elements contain caption, caption button, scrollbar, selected item, invalid item, highlight item, hot item, object of 3D, etc. Apparent attributes of window elements contain color, size, font, etc. Renderer of window can customize the size, color, picture, font of window element to give user the convenience to design individual window apparent style. User can use a special renderer to draw a main window or a control and also can develop his/her own LF renderer by customizing the metrics, color, font, and icon of window elements to get more beautiful user interface.

At present, MiniGUI provides four apparent styles for the render of window and control. The four styles are: Classic, Flat, Fashion and Skin. User can configure MiniGUI to one of the styles through a configure option.

- **Classic**: The user interface of this style renderer is similar to Windows 95 window apparent style and is the most widely used renderer in all renderers. Figure 2.1 shows the user interface rendered by classic renderer.

  ![Figure 2.1 Default renderer of MiniGUI(Classic renderer)](image)

- **Fashion**: This renderer uses the gradient filling function offered by mGPlus a component of MiniGUI V3.0 to rend the window and controls, so user can obtain very splendid graphics interface. Figure 2.2 shows the effect of fashion renderer.
Flat: The user interface drawn by this renderer is very clear and concise. This renderer is fit for monochromatic screen and gray screen. Because of simple rendering and low resource consumption, the running speed of this renderer is the fastest in all renderers. Figure 2.3 shows a main window rendered by flat renderer.

Skin: Renderers introduced above is almost realized by code, so they are light and flexible. But the difference between the devices in embedded application area is giant. Some devices have very high performance. On these device, user can use skin renderer to beautify the user interface. Skin renderer needs a complete set of picture relevant to user interface that will consume some store resource. The advantage of skin renderer is that it makes user can custom the user interface by substituting the origin pictures of system with pictures designed by user himself/herself. Figure 2.4 shows the effect of skin renderer.
Support for BIDI Text

In addition to languages that we are familiar with are written from left to right (such as English and Chinese), there are some languages are written from right to left, like Arabic and Hebrew. To support these languages, MiniGUI 3.0 provides support for two language character sets for Arabic and Hebrew and BIDI text rendering. MiniGUI 3.0 also provides the keyboard layouts for these two languages. Figure 2.5 shows an example of BIDI text.

Irregular window

In the previous version of MiniGUI, all the windows only can be rectangular. MiniGUI 3.0 provides support for irregular window, such as round rectangular window and non-rectangular window. By using the irregular window, the user interface display effect can be more amazing. Figure 2.6 shows a irregular window and irregular controls.
Enhanced font support

In MiniGUI 3.0, FMSOft introduces a new UNICODE font file format, known as the "UPF" font. The most important feature of this font is to facilitate use in the multi-process environment. It can reduce the memory footprint of MiniGUI-Processes runtime mode. At the same time, FMSOft has enhanced VBF font format, VBF font has been upgraded to 3.0. VBF 3.0 can define the glyphs for Arabic and other languages.

Others

MiniGUI 3.0 offers support for the customization of desktop. Through the external programming interface, the user can place icons on the desktop and respond to the desktop events, then achieve an effect similar to the Windows desktop. In addition, MiniGUI 3.0 also enhances the control of transparency to make it more efficient and does not depend on the internal controls’ implementation. At last, MiniGUI 3.0 provides independent scrollbar control and a unified virtual frame buffer support.

In addition, new components including mGUtils, mGPlus, mGNCS, and mGEff are added to MiniGUI. MiniGUI V3.0 also unifies the management of resource include font, bitmap, icon and cursor, because the inner resource mode and non-inner resource mode are the same effect to MiniGUI. Figure 2.7 shows a customized desktop and difference between transparent control and opaque control.
3. System Requirements to Run MiniGUI

Operating Systems Supported by MiniGUI

MiniGUI can run on any embedded operating system which supports multi-tasks in theory; now it has been proved that MiniGUI can run on Linux, uClinux, VxWorks, eCos, uC/OS-II, pSOS, ThreadX, Nucleus, and OSE smoothly. MiniGUI can also run on Win32 platform. At the same time, MiniGUI provides identical APIs on different operating systems.

Hardware Platforms Running MiniGUI

In theory, running MiniGUI is independent of the underlying hardware platform; as long as there is one supported operating system running on one hardware platform, MiniGUI can run on the hardware platform. MiniGUI can run on many popular embedded hardware platforms such as Intel x86 32/64-bit, ARM 32/64-bit (e.g., ARMv7 and ARM Cortex-A7), MIPS, PowerPC, and M68k (DragonBall/ColdFire), and so on.

Footprint of MiniGUI

MiniGUI takes few resources itself; with embedded Linux as an example, the storage and memory sizes typical used by MiniGUI are as follow:

- OS kernel: 300KB~500KB (decided by the system requirements)
- File system: 500KB~2MB (decided by the system requirements)
- MiniGUI library: 500KB~900KB (decided by the configuration options)
- MiniGUI fonts, bitmaps, and other resources: 400KB (decided by the applications, the minimum is 200KB)
- Applications: 100KB~2MB (decided by the system requirements)

The total static memory used by MiniGUI will be about 2MB to 4MB. On some systems, especially on traditional real-time operating systems, full-featured MiniGUI only uses 1MB static memory.
4. Software Architecture of MiniGUI

Software Architecture of MiniGUI

Why MiniGUI can run well on so many embedded systems? The reason is that MiniGUI has a good software architecture. MiniGUI separates the application layer and the system layer via the software abstract layer (also call portable layer). The relationship between MiniGUI and real-time operating systems is illustrated in figure 4.1. An application based on MiniGUI can implement its functions by calling APIs of ISO C library and MiniGUI libraries, and function interfaces of system and drivers. The graphics abstract layer and the input abstract layer of MiniGUI hide the details of underlying hardware and operating systems, so the applications need not to take care of the output and input devices. Besides, the special concept of MiniGUI runtime mode provides convenience to run MiniGUI on different operating systems.

![Software architecture of MiniGUI](image)

Figure 4.1 Software architecture of MiniGUI
From the above figure, we can find that from the bottom layer to top layer, MiniGUI is composed of several modules shown as below:

- Graphics abstract layer, GAL. GAL abstracts graphical interface of different device and system, providing uniform graphical interface for upper layer of MiniGUI. GAL includes software module aiming at FB device of Linux and LCD device of eCos etc. This software modules call interfaces of low level device to realize concrete operations of GAL, such as open and close of device, set of resolution and display mode. We call this software module adapting interface of GAL as engine similar to device driver of system.

- Input abstract layer, IAL. Like GAL, IAL abstract all input device, such as keyboard, keypad, mouse, touch screen to provide uniform interface for upper layer. To support keyboard, touch screen and mouse, user needs to realize input engine for this device in IAL. Through IAL and the engines in IAL, MiniGUI can support input device such as, console(keyboard and mouse), touch screen, remote controller, keypad etc..

- Graphics abstract interfaces, GDI. GDI is based on GAL providing graphical interface for application, such as curve drawing, text output, rectangle filling and so on. GDI also includes other independent sub-modules, for example, font and charset, image etc..

- Message process module. This module is on the basis of IAL. It realizes the message process mechanism and provides complete message manage interfaces for applications. As is well known, almost all GUI system is driven by event. The running of system and application is based on the message management module.

- Windowing module and control/widget module. On the basis of GDI and message process module, MiniGUI realizes the windowing module and control/widget module. This module supplies base interface for creating main window and control, and manages the control class. Control class is a important concept of reusing code of control. By using control class, user can create a number of instances of a control class. All this instances use same code of the control class. In this way, we achieve a similar concept of class and instance of C++ and able to maximize reuse existing code, and improve the maintainability of the software. MiniGUI control module has realized common controls, such as static, buttons, edit box, list box, drop-down box, and so on.

- Look and Feel. This module is interface provided to application by MiniGUI V3.0 and can be used to customize MiniGUI window and the control rendering. In the previous version, the custom to main window and control has not yet been pulled out to form an independent module, but we can still let the main window and controls have three show style through the configure option of MiniGUI. The three show styles are a similar PC-style three-dimensional (PC3D), flat-style (FLAT), popular style (FASHION). In MiniGUI 3.0, the appearance of main window and controls can be entirely customized by applications. When create main window or control, user can let the main window or control has different appearance by specifying different renderer name for them.

Modules above comprise the core of MiniGUI. Based on the interface of MiniGUI, MiniGUI provides several components for application. The components are mGUtils, mGPplus, mGEff, mGNCS, mGNC4Touch, mGi, mGp, and mG3d. These components provide extra functions for application. We will make a detail introduce for these components in subsequent sections.

The Runtime Modes of MiniGUI

Different from the general-purpose operating system like Linux, the traditional embedded operating systems have some particularities. For example, uClinux, uC/OS-II, eCos, and ThreadX usually run on non-MMU CPUs, without support for processes that have separate address spaces but only threads or
tasks. Therefore, the runtime environments are entirely different. Therefore, we need configure and compile MiniGUI into three runtime modes for different operating systems:

- **MiniGUI-Threads**: A program running on MiniGUI-Threads can create multiple cascaded windows in different threads, and all the windows belong to a single process or run in the same memory address space. MiniGUI-Threads is fit for most traditional embedded systems such as VxWorks, ThreadX, Nucleus, OSE, pSOS, uC/OS-II, eCos and so on. Of course, MiniGUI can also run on Linux/uClinux in this mode.

- **MiniGUI-Processes**: In opposition to MiniGUI-Threads, a program running on MiniGUI-Processes is an independent process, which can also create multiple windows. MiniGUI also has realized the multi-process window system. MiniGUI-Processes are fit for full-featured UNIX-like operating systems, such as Linux. This mode is provided in MiniGUI V2.0.X and is strengthened in MiniGUI V3.0. The details of this mode will be show in the below.

- **MiniGUI-Standalone**: In this mode, MiniGUI is running in a single task, does not need either multithread support or multi-process support. This mode is fit for simple application area which support only one function at one time. Example, some products use uClinux as their operate system that lack multithread support for some reason. In this conditions, you can develop applications in this mode.

MiniGUI can almost run on all operating systems under MiniGUI-Standalone mode theoretically. MiniGUI-Threads is suitable for real-time operating systems, which provide support for multi-task, or general-purpose operating systems with full-featured UNIX-like such as Linux, UNIX. MiniGUI can only run on UNIX-like operating systems under MiniGUI-Processes mode, like Linux.

No matter which mode is used, MiniGUI provides for applications the furthest compatibility; only a few initialization interfaces are different among different runtime modes.

The Runtime Mode MiniGUI-Processes

MiniGUI-Processes is a successor of MiniGUI-Lite. It offers full-featured support for multi-process embedded operating systems, such as Linux. The runtime mode MiniGUI-Lite offered by MiniGUI V1.6.x and previous versions is designed for multi-process environment of Linux; we can run several client processes on the basis of efficient client/server architecture, and make use of superior features like address space protection. With MiniGUI-Lite runtime mode, the flexibility, stability, and scalability of embedded system based on MiniGUI will improve greatly. For example, we can run several MiniGUI client processes on MiniGUI-Lite, and if one process terminates abnormally, other processes will still run well. Moreover, on MiniGUI-Lite, it is convenient for us to integrate third-party applications. Actually, this is why many embedded device developers use Linux as their operating system.

Although MiniGUI-Lite runtime mode provides support for multi-process, it cannot manage windows created by different processes at one time. Therefore, MiniGUI-Lite distinguishes windows in different

---

3 Before MiniGUI V2.0 this runtime mode is called “MiniGUI-Lite”. MiniGUI-Lite provides a tradeoff for Linux system in multi-process environment, but does not solve the overlap of windows that are from different processes. The MiniGUI-Processes runtime mode of MiniGUI V2.0 provides full-featured windowing solution for multi-processes environment.

4 At present, we only offer the MiniGUI-Standalone runtime mode for Linux/uClinux operating system.
processes by layers. This method fits for the most embedded devices with low-resolution screen, but brings some problems for application development.

MiniGUI V2.0.x solves this problem completely. On the MiniGUI-lite mode, MiniGUI V2.0.X realizes a window system in complete multi-process environment, in which every window belongs to different process can be displayed on the same desktop at one time. MiniGUI V3.0.x not only entirely inherit the MiniGUI-processes mode of MiniGUI V2.0.x but also make user can define the icon on the desktop and respond the event of desktop. So, the user can customize the desktop conveniently. Figure 4.2 gives the screenshots of MiniGUI-Lite runtime mode of MiniGUI V1.6.x and MiniGUI-Processes runtime mode of MiniGUI 3.0.x.

![Screenshot of MiniGUI-Lite runtime mode of MiniGUI V1.6.x and MiniGUI-Processes runtime mode of MiniGUI 3.0.x](image)

In the first screenshot of Figure 4.2, we run two client processes: vcongui and housekeeper. It is obvious that after housekeeper started, we could not see the windows of vcongui; in the second screenshot, we run three client processes: vcongui, picview, and housekeeper, but we can see all windows created by these three clients.

Compared with MiniGUI-Lite, MiniGUI-Processes runtime mode has obvious advantages. So MiniGUI is not only useful for traditional embedded system (MiniGUI-Threads), but also useful for embedded system with multi-process features, such as Linux. Besides, MiniGUI-Processes keeps the concept of layer in MiniGUI-Lite. You can put windows of different client processes into different layers. By using layer, we can create many workspaces for different processes like X Window, whereas, the footprint of MiniGUI-Processes is far less than X Window. With the MiniGUI-Processes runtime mode, MiniGUI will not only can extend its application fields in high-end embedded devices, but also can be applied in desktop environment.

Windowing System

In MiniGUI, windows are generally organized in the form of hierarchy; the root window is the ancestor of all windows, all the other windows have parent windows except the root window, and each window may have child windows, brother windows, ancestor windows, or descendant windows, etc. Windows of the same level can be overlapped, but only one window can output to the overlapped region at one time.

MiniGUI has three window types: main window, dialog box, and control window (child window). The main window generally includes some child windows, and these child windows are generally MiniGUI built-in controls or user-defined controls. An application can also create main windows of other types such as dialog boxes or message boxes. A dialog box is actually a main window, and the application usually interacts with the user by using a dialog box.

Communication Mechanism

The communication mechanism of MiniGUI is similar to Win32’s. The Figure 4.5 illustrates the mode of the way that how the messages transferring in MiniGUI-Thread runtime mode. Therein, Desktop thread acts as a micro-server, all of the messages fetched from Event thread will be sent to Desktop thread first, and then be dispatched to the target windows by Desktop thread.
Comparing MiniGUI-Threads, the messages transferring mode of MiniGUI-Processes is implemented by UNIX socket. The communication mechanism is illustrated by Figure 4.6.

Fonts

MiniGUI supports for multiple character sets and multiple fonts. At present, what are supported include such charsets/encodings as ISO8859-1 ~ ISO8859-15, GB2312, BIG5, EUCKR, SHIFT-JIS. The font types include bitmap fonts (RBF, VBF, QPF) and vector fonts, such as TrueType, Adobe Type1. MiniGUI’s VBF font can be used to display special characters like Thai characters. MiniGUI can also zoom in the font glyphs automatically. For some special displaying equipment like TV set, MiniGUI also provides the anti-alias feature for font rendering.

MiniGUI V3.0 supports the new device font (bit-map font), which can provide other logical font APIs for applications and controls. The font glyphs can be defined by customized bitmaps. The font of VBF V2.0 has been updated to VBF V3.0. The VBF V3.0 hasn’t been limited by supporting Latin character sets. The font-type number of single VBF font hasn’t been limited to the inside of 255. The UPF font is the optimized release of QPF, which reduces the use of memory in the MiniGUI processes, and is convenient to using by the way of memory map. It provides BIDI text output and input for user, including Arabic (ISO8859-6), Hebrew (ISO8859-8).

Support of Input Devices
MiniGUI supports various common mouse/touch-panel devices. MiniGUI also provides excellent support with a calibration interface for touch-panel.

MiniGUI supports multiple keyboard layouts, including American PC, French, German, Italian, Spanish, and so on.

Except the common input devices, MiniGUI can provides support for various input devices, which are popular in embedded devices, such as remote controllers, keypads, buttons, and so on.

**Input engines**

The graphical engine of qvfb and wvfb brings some convenience to users in the developing MiniGUI. As an independent application program, the graphical engine causes a lot of inconveniences, such as virtual framebuffer program starting up single, users setting the display mode necessarily, and only starting one MiniGUI application program in the mode of MiniGUI-Threads and MiniGUI-Standalone. Theoretically, different application programs can run at different virtual framebuffers. MiniGUI V3.0 solves this problem by integrating the virtual framebuffer graphical engines into xvfb, which make users run programs easily by xvfb.

**Internationalization**

MiniGUI supports charsets of ISO8859-1～ISO8859-15, GB2312, GBK, GB18030, BIG5, EUCKR, EUCJP, Shift-JIS, UNICODE, etc. The inner encode of support for these charsets is non-UNICODE, so the support consumes fewer resource and fits better for embedded system.

MiniGUI fully supports for UNICODE (a international standard charset), so it is convenient for developer to apply a lot of languages in their application such as English, Chinese, Korean, Japanese and other languages supported by UNICODE. MiniGUI V3.0 newly supports BIDI text, such as Arabic (ISO8859-6), Hebrew (ISO8859-8).

While developing MiniGUI applications, if only need to display words of one charset, for example, simplified Chinese (GB2312), you only need configure MiniGUI to enable GB2312 charset and some fonts for the charset. In this way, you can reduce the resources consumed. If you want to display characters in several charsets at the same time, such as Japanese and Korean, you can enable UNICODE in MiniGUI set font which support UNICODE, for example, TrueType fonts or QPF fonts. In this case, application needs to do nothing but to set logical font with right charset. MiniGUI can convert the certain characters in one charset(such as GB2312, GBK) to UNICODE automatically and select the relevant fonts to render the text. This realization mode is different from traditional mode which uses UNICODE as inner encode. The traditional mode need to translate characters from other charset to UNICODE before the characters being rendered rightly.

5. Components of MiniGUI

To meet the various needs of different embedded devices, FMSof has developed a number of components based on MiniGUI. Users of these products, components, MiniGUI to expand the functions and can have a good MiniGUI application integration.

mGUtis
mGUtils provides users with several commonly used function templates, so user do not need to implement these functions again. Function templates are listed below:

- **Common file dialog box.** This template dialog box has file open, file save, and file save as function. It’s appearance has two modes: simple model and PC model. As long as the user set up the FILEDLGDATA data structure, and call the relevant function, he/she can implement the corresponding function. It’s easily to use.

- **Color settings dialog box.** This template dialog box is absolutely useful when you need to provide color palette for application. Color setting dialog box also has simple model and standard PC model. As long as the user set up the COLORDLGDATA data structure, and then call the color setting dialog box interface function, user can get a beautiful color setting user interface. It’s a piece of cake to realize.

- **Font settings dialog box.** This template provides a font settings dialog box same as Windows’s font set dialog box. The role of font setting dialog box in the application development is well known to very developer. To realize the font setting dialog box, user only need to set up the FONTDLGDATA data structure at first, and then call the font setting function.

- **Information set dialog box.** This template provides a dialog box to show special information. With this template, users do not have to develop a dialog box to show pop-up information. Setting up the INFODLGDATA data structure, then user can call the template function shows the information.

Figure 5.1 shows the color setting dialog box and file dialog box.

![Figure 5.1 mGUtils: Color Setting Dialog Box and File Dialog Box](image)

**mGPlus**

mGPlus is an expanding and enhancement to graphical interface of MiniGUI, mainly on the provision of two-dimensional vector graphics and advanced graphics algorithm support, such as path, gradient filling and color composite.

- **Path.** The path is comprised of a set of broken lines and curves with strict order. Paths can be used for filling and cutting. By providing support for the path, we can realize many functions on vector graphics such as drawing, limitless zooming and rotate etc., and also we can provide better support for vector font.

- **Gradient fill.** Gradient fill is a kind of filling which uses a painting brush that it’s color changes linearly or according to a path to fill in a designated area or a region of a path or a graphic. With
gradient filling, we can implement more beautiful and more stereo control. At present, MiniGUI provides two modes of gradient filling: linear gradient filling and radial gradient filling.

✓ Color composition: In today, product packaging has been attached great importance. Every application developer hopes to develop a very pretty sophisticated user interface to obtain user's first good impression. Color composition can be a potent weapon in this regard. It can make an ever-changing composition between pictures, giving you a amazing user interface effect. MiniGUI 3.0 has implemented 12 kinds of patterns of color composition.

Figure 5.2 illustrates path, color composition, and color gradient filling separately.

Figure 5.2 mGPlus: path, color composite, and color gradient filling

mGEff

mGEff provides an animation framework for MiniGUI applications. mGEff provides a lot of stable and efficient effectors, which can be used to implement the animations like flipping, zooming, scrolling, and so on. Furthermore, by using the double buffer provided by MiniGUI 3.0, mGEff provides the animation APIs for MiniGUI main windows.

mGNCS

In the development of miniStudio, in order to realize the design of visual graphic interface, based on MiniGUI existing interfaces, FMSoft developed a new control set. The new control set introduced by miniStudio is developed on the foundation of the original MiniGUI control set. In order to distinguish it from MiniGUI intrinsic control set, it is referred to as “new control set”, and we release it as a new MiniGUI component: mGNCS.
Features of the new control set are as follows:

- Object-oriented programming idea is adopted to rearrange the inheritance relations between the controls. C language is used to realize concepts similar to C++ class, and C language interface is provided externally. In this respect, the new control set introduced by mStudio is similar to the control set of Gtk+.
- Interfaces and styles of the controls are standardized, enabling all controls to access with uniform interface.
- Based on MiniGUI 3.0 look and feel renderer, the concept of look and feel renderer is further expanded. Each control in the new control set has its own look and feel renderer and exclusive renderer interface of each control is defined according to the inheritance rule of the controls, enabling them to change along with the changes of controls.

Through developing the new control set, we settle the deficiencies of MiniGUI intrinsic control set in the following aspects simultaneously:

- The interfaces are not uniform and standardized;
- Operating controls through messages, it is difficult to maintain codes and easy to make mistakes;
- Hierarchical relation of intrinsic control is unclear, there are many repeated codes, and it is inconvenient to customize and extend control functions;
- Drawing efficiency of the intrinsic control is low, and twinkling problem is serious when running on the development board.

You can mix mGNCS controls and MiniGUI original controls in your applications. However, we strongly encourage and recommend that you use mGNCS as the framework for your new MiniGUI apps.

Legacy Components

Note that the legacy components only support MiniGUI V3.0.x. We will not maintain these legacy components for MiniGUI V3.2.x or later.

mGp

mGp is a printing component of MiniGUI, which provides a printing function to MiniGUI applications. At present, mGp supports Epson, HP and some other printers. Figure 5.3 shows the setup window of mGp.
mGi

mGi is a input component of MiniGUI, which provides the framework of soft-keyboard and handwrite input methods. It also supplies an IME container for users to add self-defined IME to it. In addition, you can use self-defined keyboard bitmap for the soft-keyboard and add self-defined translation method to it. Figure 5.4 and Figure 5.5 illustrate the user interfaces of input methods of soft-keyboard and handwrite respectively.

![Figure 5.4 mGi: input with soft-keyboard](image)

![Figure 5.5 mGi: input with hand writing](image)

mG3d

mG3d is a 3D rendering component of MiniGUI providing 3D interface for applications. Using this component, you can render 3D images, 3D words and 3D scene in your applications. Figure 5.6 shows some 3D objects created by mG3d.

6. Development Tools

miniStudio: the Integrated Development Environment for MiniGUI

miniStudio is an Eclipse-based integrated development environment (IDE) for MiniGUI. miniStudio provides a WYSIWYG GUI designer for developers. It can generate and maintain MiniGUI apps easily. You can use miniStudio to edit code, compile, run, debug your MiniGUI apps.

miniStudio is a shareware, you can download, install, and use it for free.

miniStudio provides the following features:

- Based on Eclipse SDK 4.7.2, C/C++ Development Tooling (CDT) 9.3.
- The GUI Designer, which is developed based on MiniGUI, provides the WYSIWYG ability.
- The new MiniGUI app framework which is based on mGNCS, the new control set for MiniGUI. miniStudio provides more than 30 built-in controls. You can also import the third-party widget components into miniStudio. This provides a great scalability for the development of MiniGUI apps.
- We introduce the concept of widget renderer. By designing a renderer, the logic and draw of widget will be separated. You can give a different appearance for a widget by using a different renderer without programming.
- Unified resource management. A GUI application usually is composed of code and resources. The resources, including images, text, windows, strings, and user-defined resources, are managed by unified IDs in miniStudio.
- Provide event-listener, data source, and data binding mechanisms. With event-listener mechanism, one object could listen events of another object; the relation of properties between two objects could be created by data binding mechanism; the UI and data could be separated with data source mechanism. Currently, miniStudio supports the three data source types: text files, XML, and SQLite.

Figure 6.1 shows the built-in widgets provided by miniStudio.

![Figure 6.1 The built-in widgets provided by miniStudio](image-url)
Figure 6.2 gives a runtime screenshot of miniStudio.

At present, the latest version of miniStudio is V1.2.1. You can download it from the official website of MiniGUI.

Legacy developing mode of MiniGUI

The MiniGUI application can be developed under Linux or Windows environment. Since MiniGUI is written totally in C, it’s an easy job to cross-compile and port MiniGUI and its applications to a different hardware platform.

An application for embedded devices can be cross-compiled in the host which installed the specified tool chain for a certain embedded device. The most common way is installing a cross compiler inherited from gcc and cross-compiling the application. If your operating system is VxWorks or UC/OS-II, you should install the relevant IDE (such as Tornado or ADS) in Windows, and compile your applications by using the IDE.

If you develop MiniGUI applications in Linux environment, there are two ways to run them after compiling, one is running MiniGUI on Linux console (you must make sure that the kernel built with the support for framebuffer), the other is running MiniGUI on qvfb or gvfb, which are a virtual framebuffer simulator running on X11).

If you develop MiniGUI applications under Windows environment, you can compile them by using Visual Studio IDE, then running the applications on wvfb (A framebuffer simulator running on Windows). Please see Figure 6.3.
Running MiniGUI applications in simulator or console directly, it is convenient to develop embedded application and you can avoid to run programs on embedded devices frequently. The standard debugger is also used to running embedded application in developing host.

7. MiniGUI Resources

You can visit the following web site to download the official release tarballs of MiniGUI and its components, as well as the samples and some open source software run on MiniGUI:

8. Roadmap of MiniGUI

The following features will be provides in the near future:

- The MiniGUI implementation of EGL API for OpenGL ES 1.1/2.0 (Derived from the latest Mesa3D release).
An enhanced Linux graphics engine which uses DRI (Direct Rendering Interface).

A framework for stacked UIs (based on mGEff, mGNCS, and mGPlus/Mesa3D). This will bring the modern UI effects and animations which are popular in smart phones (iOS or Android) into Linux-based embedded systems and smart IoT devices.

Some enhancements of miniStudio.

As a long-term plan, we will try to provide a Python-based runtime framework for smart devices which based on Linux and MiniGUI.

9. Licensing Policy of GPL’d MiniGUI

FMSof releases some versions of MiniGUI under GPL (General Public License). So any application linking to GPL’d MiniGUI must follow GPL. If you cannot accept GPL or don’t want accept GPL, you need to be licensed from FMSof.

Free Use for Those Who Are 100% GPL

If your application is licensed under GPL, you need not to be authorized by Feynman. Any one is welcome to copy, modify and release MiniGUI following GPL. For doing this, you do not need a separate signed agreement with FMSof, because the GPL text is sufficient. But you also need to pay a attention to that Feynman will not give any kinds of warranty or support service in this case.

Free Use for Those Who Never Copy, Modify or Distribute

As long as you never distribute (internally or externally) the MiniGUI in any way, you are free to use it for powering your application, irrespective of whether your application is under GPL license or not. Of course, there is on warranty and support service from Feynman.

More specifically:

- Modifying - You are allowed to modify MiniGUI source code any way you like. If you distribute the modified version, all changes, all interface code and all code that connects directly or indirectly to the interface code fall under GPL.
- Copying - You are allowed to copy MiniGUI binaries and source code, but when you do so, the copies will fall under the GPL.

Commercial Use for Everyone Else

If your application is not licensed under GPL and you intend to distribute MiniGUI software or function library (be that internally or externally), you must first obtain a commercial license to the MiniGUI software in question.

More specifically:

- If you link MiniGUI in your non-GPL application, you need a commercial license for the MiniGUI library.
- If you use MiniGUI library within your organization and you don’t want to risk it falling under the GPL license, you are welcome to purchase a commercial license.
Many users may choose the commercial license simply because in this way FMSoft takes responsibility for its products. Under the GPL license, there are no warranties or representations from the developer (i.e. from FMSoft).

Mode of commercial authorization, price and way to purchase are shown in the following web:

http://www.minigui.com

For commercial application software developers, we provide value-added release version of MiniGUI which is used to support non-GPL application during developing phase of software product.
